**WARNING:** THIS PRODUCT IS FOR RESEARCH ONLY - NOT FOR HUMAN OR VETERINARY DIAGNOSTIC OR THERAPEUTIC USE.
Safety Data

This material should be considered hazardous until further information becomes available. Do not ingest, inhale, get in eyes, on skin, or on clothing. Wash thoroughly after handling. Before use, the user must review the complete Safety Data Sheet, which has been sent via email to your institution.

Precautions

Please read these instructions carefully before beginning this assay.

If You Have Problems

Technical Service Contact Information

Phone: 888-526-5351 (USA and Canada only) or 734-975-3888
Fax: 734-971-3641
Email: techserv@caymanchem.com
Hours: M-F 8:00 AM to 5:30 PM EST

In order for our staff to assist you quickly and efficiently, please be ready to supply the lot number of the kit (found on the outside of the box).

Background

β-Hydroxybutyrate (β-HB; 3-hydroxybutyric acid) is a "ketone body" which is produced in the liver, mainly from the oxidation of fatty acids, and is exported to peripheral tissues for use as an energy source. The term 'ketone body' refers to three molecules, acetoacetate, β-HB, and acetone. β-HB and acetoacetate transport energy from the liver to the other tissues and acetone is generated by spontaneous decarboxylation of acetoacetate. The presence of ketosis may be normal or pathologic. Normally ketosis can indicate that lipid metabolism has been activated and the pathway of lipid degradation is intact. Normal ketosis is prevalent in many circumstances such as during fasting, after prolonged exercise or after a high fat diet. Pathological causes of ketosis include multiple organ failure, diabetes, childhood hypoglycemia, corticosteroid or growth hormone deficiency, intoxication with alcohol or salicylates and several inborn errors of metabolism.

In acutely ill patients, these ketone bodies can accumulate in the body to cause ketoacidosis, which leads to the potentially life threatening condition known as metabolic acidosis. The presence and degree of ketosis can be determined by measuring blood levels of β-HB. Ordinarily, β-HB accounts for approximately 75% of the ketone bodies in serum.

Measurement of β-HB provides a reliable index of the level of ketoacidosis, including the detection of subclinical ketosis. In diabetics, β-HB measurements (and blood glucose) can be used for the assessment of the severity of diabetic coma and is essential for the exclusion of hyperosmolar non-ketotic diabetic coma. The measurement of β-HB is also used to monitor insulin requirements, based on existing hyperketonemia. β-HB has more recently been evaluated for use in neurodegenerative diseases and inhibition of adipocyte lipolysis.
About This Assay

Cayman’s β-HB (Ketone Body) Colorimetric Assay Kit provides a simple, reproducible, and sensitive tool for measuring β-HB levels in plasma, serum, urine, cell lysates, or tissue homogenates. The method for β-HB determination is based upon the oxidation of D-3-hydroxybutyrate to acetoacetate by the enzyme 3-hydroxybutyrate dehydrogenase. Concomitant with this oxidation, the cofactor NAD$^+$ is reduced to NADH. In the presence of diaphorase, NADH reacts with the colorimetric detector WST-1 to produce a formazan dye with an absorbance maximum at 445-455 nm (see Figure 1 on page 7). The absorbance of the dye is directly proportional to the β-HB concentration.

Figure 1. Assay scheme
Sample Preparation

β-HB concentrations in plasma and serum can vary over a rather wide range, with normal levels measuring 0.02-1.5 mM and increasing to as high as 3-5 mM in diabetics. β-HB concentrations in urine can be as high as 30-50 mM during diabetic ketoacidosis.6,7,17,18

Plasma
1. Collect blood using an anticoagulant such as heparin, EDTA, or citrate.
2. Centrifuge the blood at 700-1,000 x g for 10 minutes at 4°C. Pipette off the top yellow plasma layer without disturbing the white buffy layer. Store plasma on ice. If not assaying the same day, freeze at -80°C. The plasma sample will be stable for one month while stored at -80°C.
3. Plasma should be diluted 1:5-1:10 with Assay Buffer before assaying.

Serum
1. Collect blood without using an anticoagulant.
2. Allow blood to clot for 30 minutes at 25°C.
3. Centrifuge the blood at 2,000 x g for 15 minutes at 4°C. Pipette off the top yellow serum layer without disturbing the white buffy layer. Store serum on ice. If not assaying the same day, freeze at -80°C. The serum sample will be stable for one month while stored at -80°C.
4. Serum should be diluted 1:5-1:10 with Assay Buffer before assaying.
Urine
1. Collection of urine does not require any special treatment. If not assaying the same day, freeze at -80°C.
2. Urine should be diluted 1:10 with Assay Buffer before assaying.

NOTE: β-HB values from urine samples can be standardized using Cayman’s Creatinine (urinary) Assay Kit (Item No. 500701).

Cell Samples
1. Collect cells (~18 x 10^6 cells) by centrifugation (i.e., 1,000-2,000 x g for 10 minutes at 4°C). For adherent cells, do not harvest using proteolytic enzymes; rather use a rubber policeman.
2. Resuspend cell pellet in 1-2 ml of cold Assay Buffer.
3. Sonicate the cell suspension 20X at 1 second bursts.
4. Centrifuge cell suspension at 10,000 x g for 10 minutes at 4°C.
5. Remove the supernatant and store on ice. If not assaying on the same day, freeze at -80°C until use. The sample will be stable for at least one month. No further dilution is needed before assaying.
6. Resuspend the pellet in 1 ml of cold Assay Buffer and store on ice. If not assaying on the same day, freeze at -80°C until use. The sample will be stable for at least one month. Prior to assaying, dilute the sample 1:2-1:5 with cold Assay Buffer.

Tissue Samples
1. Weigh tissue and then mince into small pieces.
2. Homogenize 350-400 mg of minced tissue in 2 ml of the Assay Buffer containing protease inhibitors of choice (see Interferences section).
3. Centrifuge at 1,000 x g for 10 minutes at 4°C.
4. Transfer the supernatant to another tube and centrifuge at 10,000 x g for 10 minutes at 4°C.
5. Remove the supernatant and store on ice. If not assaying on the same day, freeze at -80°C until use. The sample will be stable for at least one month. No further dilution is needed before assaying.
6. Resuspend the pellet in 1-2 ml of cold Assay Buffer and store on ice. If not assaying on the same day, freeze at -80°C until use. The sample will be stable for at least one month. Prior to assaying, dilute the sample 1:2-1:5 with cold Assay Buffer.
**ASSAY PROTOCOL**

**Plate Set Up**

There is no specific pattern for using the wells on the plate. A typical layout of the β-HB standard curve and samples to be measured in triplicate is given in Figure 2. We suggest you record the contents of each well on the template sheet provided (see page 22).

**Pipetting Hints**

- It is recommended that a repeating pipettor be used to deliver reagents to the wells. This saves time and helps to maintain more precise incubation times.
- Before pipetting each reagent, equilibrate the pipette tip in that reagent (i.e., slowly fill the tip and gently expel the contents, repeat several times).
- Do not expose the pipette tip to the reagent(s) already in the well.

**General Information**

- The final volume of the assay is 100 µl in all wells.
- It is not necessary to use all the wells on the plate at one time.
- It is recommended that the samples be assayed at least in triplicate, but it is the user’s discretion to do so.
- The assay is performed at 25°C.
- Monitor the absorbance at 445-455 nm.
Standard Preparation

Take eight clean test tubes and label them A-H. Add the amount of 1 mM β-HB Standard Solution and Assay Buffer to each tube as described in Table 1. We recommend that you store these diluted Standards for no more than one to two hours.

Table 1. Preparation of β-Hydroxybutyrate standard curve

Performing the Assay

1. β-Hydroxybutyrate Standard Wells - Add 50 µl of each Standard (tubes A-H) to two or three wells (see suggested plate configuration, Figure 2, page 12).
2. Sample Wells - Add 50 µl of the sample to two or three wells.
3. Initiate the reaction by adding 50 µl of the Developer Solution to all wells being used.
4. Incubate the plate at 25°C in the dark for 30 minutes.
5. Read the absorbance at 445-455 nm using a plate reader.
Calculations

1. Calculate the average absorbance of each standard and sample.
2. Subtract the absorbance value of standard A (0 mM) from itself and all other values (both standards and samples). This is the corrected absorbance.
3. Plot the corrected absorbance values (from step 2 above) of each standard as a function of the final β-HB concentration (mM) (see Table 1, page 14). A typical β-HB standard curve is shown in Figure 3, on page 17.
4. Calculate the values of the β-HB samples using the equation obtained from the linear regression of the standard curve by substituting the corrected absorbance values for each sample into the equation.

\[
\text{β-Hydroxybutyrate (mM)} = \frac{\text{Corrected absorbance} - (y\text{-intercept})}{\text{Slope}} \times \text{Dilution}
\]

Figure 3. β-Hydroxybutyrate standard curve
Performance Characteristics

Precision:
When a series of 48 human plasma and urine samples were assayed on the same day, the intra-assay coefficient of variation was 4.05% and 3.68%, respectively. When a series of 48 human plasma and urine samples were assayed on six different days under the same experimental conditions, the inter-assay coefficient of variation was 3.18% and 3.03%, respectively.

Assay Range:
Under the standardized conditions of the assay described in this booklet, the dynamic range of the kit is 0-0.5 mM β-HB.

Interferences

The following reagents were tested in the assay for interference in the assay:

**Troubleshooting**

<table>
<thead>
<tr>
<th>Problem</th>
<th>Possible Causes</th>
<th>Recommended Solutions</th>
</tr>
</thead>
</table>
| Erratic values; dispersion of duplicates/triplicates | A. Poor pipetting/technique  
B. Bubble in the well(s) | A. Be careful not to splash the contents of the wells  
B. Carefully tap the side of the plate with your finger to remove bubbles |
| No β-HB was detected in the sample                | A. β-HB concentration was too low  
B. The sample was too dilute | Do not dilute samples and re-assay                                                    |
| Sample absorbance values are above highest point in standard curve | A. β-HB concentration was too high in the sample  
B. The sample was too concentrated | Dilute samples with Assay Buffer and re-assay; NOTE: *Remember to account for the dilution factor when calculating β-HB concentration* |
